a. `01-Apr-22`

b. `22-Apr-01`

c. `Apr-01-22`

d. The code will throw an exception at runtime.

Q46 Given the following code:

Click here to view code image

```
public class TestX {
  public static void main(String[] args) {
    System.out.println(action(Integer.valueOf("1")));
  }
  public static boolean action(Object obj) {
    return (obj instanceof String value1 && value1.contains("1") ||
            obj instanceof Integer value2 && value2.intValue() < 1);
    }
}
```

What is the result?
Select the one correct answer.

a. `true`

b. `false`

c. The program will throw an exception at runtime.

d. The program will fail to compile.

Q47 Given the following code:

Click here to view code image

```
import java.time.Duration;
public record Song(String title, Duration duration) {
  // (1) INSERT CODE HERE
}
```

and

Click here to view code image

```
public class TestY {
  public static void main(String[] args) {
    Song song = new Song("Imagine", 106);
    System.out.println(song);
  }
}
```

Which option can be inserted into the `Song` record declaration at (1), so that the program will print `Song[title=IMAGINE, duration=PT1M46S]`?
Select the one correct answer.

a. Click here to view code image

```
 public Song(int seconds) {
      this(this.title.toUpperCase(), Duration.ofSeconds(seconds));
   }
```

b. Click here to view code image

```
public Song(int seconds) {
     this(title.toUpperCase(), Duration.ofSeconds(seconds));
   }
```

c. Click here to view code image

```
public Song(String title, int seconds) {
     this(title.toUpperCase(), Duration.ofSeconds(seconds));
   }
```

d. Click here to view code image

```
public Song(String title, int seconds) {
     this.title = title.toUpperCase();
     this.duration = Duration.ofSeconds(seconds);
   }
```

e. Click here to view code image

```
public Song {
     this.title.toUpperCase();
     this.duration = Duration.ofSeconds(seconds));
   }
```

Q48 Given the following directory structure under the directory `./Sun`:

Click here to view code image

```
./Sun/1_Mercury
./Sun/2_Venus
./Sun/3_Earth
./Sun/3_Earth/1_Moon
./Sun/4_Mars
./Sun/4_Mars/1_Phobos
./Sun/4_Mars/2_Deimos
./Sun/5_Jupiter
./Sun/5_Jupiter/1_Io
./Sun/5_Jupiter/2_Europa
./Sun/5_Jupiter/3_Ganymede
./Sun/5_Jupiter/4_Calisto
./Sun/6_Saturn
./Sun/7_Uranus
./Sun/8_Neptune
```

and the code:

Click here to view code image

```
try {
  Path sun = Path.of("./Sun");
  Files.walk(sun)
       .map(p->p.getName(p.getNameCount()-1).toString())
       .sorted()
       .limit(3)
       .forEach(p->System.out.println(p.substring(2)));
} catch (IOException e) {
  e.printStackTrace();
}
```

What is the result?

Select the one correct answer.

a.

```
Io
Mercury
```

b.

```
Io
Mercury
Moon
```

c.

```
Io
Mercury
Moon
Phobos
```

d.

```
Earth
Ganymede
```

e.

```
Venus
Deimos Europa
```

Q49 Given the text file `data.txt` that contains following lines:

```
Apple:1.99
Pear:1.70
Apple:1.70
Apple:1.75
Orange:1.99
```

and the following code:

Click here to view code image

```
try {
  Path test = Path.of("data.txt");
  Map<String, List<String>> values
      = Files.lines(test).collect(Collectors.groupingBy(
                                           ln -> ln.substring(ln.indexOf(":")
  System.out.println(values);
} catch (IOException e) {
  e.printStackTrace();
}
```

What is the result?
Select the one correct answer.

a. `{1.70=[1.70, 1.70], 1.99=[1.99, 1.99], 1.75=[1.75]}`

b. `{1.70=[Pear:1.70, Apple:1.70], 1.99=[Apple:1.99, Orange:1.99], 1.75=[Apple:1.75]}`

c. `{1.70=[Pear, Apple], 1.99=[Apple, Orange], 1.75=[Apple]}`

d. `{Apple=[Apple:1.99, Apple:1.70, Apple:1.75], Pear=[Pear:1.70], Orange=[Orange:1.99]}`

e. `{Apple=[1.99, 1.70, 1.75], Pear=[1.70], Orange=[1.99]}`

f. `{Apple=[Apple, Apple, Apple], Pear=[Pear], Orange=[Orange]}`

Q50 Given the following code:

Click here to view code image

```
module travel {
  requires transport;
  uses transport.mode.TransportType;
}
```

and

```
module transport {
  exports transport.mode;
}
```

What is the correct declaration for a module named `basic` that implements the `TransportType` service?
Select the one correct answer.

a. Click here to view code image

```
module basic {
  requires travel;
  provides travel.mode.TransportType with basic.mode.Horse;
}
```

b. Click here to view code image

```
module basic {
  requires transport.mode;
  provides TransportType with Horse;
}
```

c. Click here to view code image

```
module basic {
  requires transport;
  provides transport.mode.TransportType with basic.mode.Horse;
}
```

d. Click here to view code image

```
module basic {
  requires travel.mode;
  provides TransportType with Horse;
}
```

Appendix F

Annotated Answers to Mock Exam

This appendix provides annotated answers to the questions in the mock exam for the *Java SE 17 Developer* exam found in Appendix E, p. 1709.

Annotated Answers

Q1 *(e)*

An object of the class `Extension` is created. The first thing the constructor of `Extension` does is invoke the constructor of `Base`, using an implicit `super()` call. All calls to the method `void add(int)` are dynamically bound to the `add()` method in the `Extension` class, since the actual object is of type `Extension`. Therefore, this method is called by the constructor of `Base`, the constructor of `Extension`, and the `bogo()` method with the parameters `1`, `2`, and `8`, respectively. The instance field `i` changes value accordingly: `2`, `6`, and `22`. The final value of `22` is printed.

Q2 *(e)*

Method `g()` modifies field `a`. Method `g()` modifies parameter `b`, not field `b`, since the parameter declaration shadows the field. Variables are passed by value, so the change of value in parameter `b` is confined to the method `g()`. Method `g()` modifies the array whose reference value is passed as a parameter. A change to the first element is visible after return from the method `g()`.

Q3 *(b)*

Classes cannot extend interfaces; they can implement them. Interfaces can extend, but not implement other interfaces. A class must be declared as `abstract` if it does not provide an implementation for all abstract methods of the interfaces that it implements. Instance methods that have no implementation in an interface are implicitly `public` and `abstract`. Classes that implement these methods must explicitly declare these methods to be `public`.

Q4 *(b)*

The method with the most specific signature is chosen. In this case the `int` argument `10` is boxed to an `Integer`, which is passed to the `Number` formal parameter, as type `Number` is more specific than `Object`.

Q5 *(c)*

As it stands, the program will compile correctly and will print `3, 2` at runtime. If the `break` statement is replaced with a `continue` statement, the loop will perform all four iterations and will print `4, 3`. If the `break` statement is replaced with a `return` statement, the whole method will end when `i` equals 2, before anything is printed. If the `break` statement is simply removed, leaving the empty statement (`;`), the loop will complete all four iterations and will print `4, 4`.

Q6 *(d)*

The type of `nums` is `int[][]`. The outer loop iterates over the rows, so the type of the loop variable in the outer loop must be `int[]`, and the loop expression is `nums`. The inner loop iterates over each row, `int[]`. The loop variable in the inner loop must be `int`, and the loop expression in the inner loop is a row given by the loop variable of the outer loop. Only in the loop headers in (d) are both element types compatible.

Q7 *(e)*

The loop condition `++i == i` is always true, as we are comparing the value of `i` to itself, and the loop will execute indefinitely. The evaluation of the loop condition proceeds as follows: (`(++i) == i`), with the operands having the same value. For each iteration, the loop variable `i` is incremented twice: once in the loop condition and a second time in the parameter expression `i++`. However, the value of `i` is printed before it is incremented the second time, resulting in odd numbers from 1 onward being printed. If the prefix operator is also used in the `println` statement, all even numbers from 2 onward would be printed.

Q8 *(d)*

The expression `i % k` evaluates to the remainder value `3`. The expression `i % -k` also evaluates to the remainder value `3`. We ignore the sign of the operands, and negate the remainder only if the dividend (`i` in this case) is negative.

Q9 *(c)*

Strings are immutable, so the method `concat()` does not change the state of the `s1` string. The `default` case is executed in the `switch` statement. There is no fall-through in the `switch` statement, as the switch statement uses arrow notation in which the case labels are mutually exclusive.

Q10 *(b) and (f)*

In both cases, the code in the `if` statement and the `while` loop is unreachable, so it can never be executed. In the case of the `while` loop, the compiler flags an error. The `if` statement is treated as a special case by the compiler to simulate conditional compilation, allowing code that should not be executed.

Q11 *(b)*

The thing to note is that the method `compareTo()` is overloaded in the subclass `Student`, and is not overridden. Thus objects of class `Student` have two methods with the same name: `compareTo`. For overloaded methods, the method to be executed is determined at compile time, depending on the type of the reference used to invoke the method, and the type of the actual parameters. When the type of the reference is `Person` (as is the case for `p1` and `p2`), the method `compareTo()` in `Person` will always be executed. When the type of the reference is `Student` and the argument type is `Person`, the overridden method `compareTo()` in `Person` will always be executed. The overloaded method `compareTo()` defined in the subclass `Student` is executed by the last call `s1.compareTo(s2)` in the `main()` method, where the type of the reference is `Student` and the argument type is also `Student`.

Q12 *(b) and (e)*

The `add(element)` method adds an element at the end of the list. The `add(index, element)` method adds the element at the specified index in the list, shifting elements to the right from the specified index. The index satisfies `(index >= 0 && index <= size())`. The `set(index, element)` method replaces the element at the specified index in the list with the specified element. The index satisfies `(index >= 0 && index < size())`. The `for(;;)` loop adds the elements currently in the list at the end of the list. The list changes as follows:

Click here to view code image

```
[Ada]
[Ada, Alyla]
[Ada, Otto]
[Ada, Anna, Otto]
[Ada, Anna, Otto, Otto, Anna, Ada]
```

Q13 (d)

The `add(index, element)` method accepts an index that satisfies the condition `(index >= 0 && index <= size())`. The `for(;;)` loop swaps elements to reverse the elements in the list.

Q14 (d)

In (a), the type of parameter `s` is inferred to be `String`. The new string returned by calling the `toLowerCase()` method is discarded. Only the string element `"Circle"` contains the substring `"c"` and is printed.

In (b), the raw type `Predicate` is used. The type of parameter `s` is inferred to be `Object`. The expression `s.contains("c")` in the `return` statement fails to compile since the method `contains()` is not defined in the class `Object`.

In (c), the type of parameter `s` is inferred to be `String`. Only the string element `"Circle"` contains the substring `"c"` and is printed.

In (d), the type of parameter `s` is inferred to be `Object`. The string elements are referenced by the parameter `s` of type `Object`. However, the chain of method calls is invoked on objects of type `String`, resulting in both stream elements being selected and printed.

In (e), the raw type `Predicate` is used. The type of parameter `s` is inferred to be `Object`. The statement fails to compile since the method `contains()` is not defined in the class `Object`.

In (f), the raw type `Predicate` is used. The type of parameter `s` is inferred to be `Object`. The class `Object` does not define the method `toLowerCase()` and the statement fails to compile.

Q15 (b)

A functional interface is an interface that has only one abstract method, aside from the abstract method declarations of `public` methods from the `Object` class. This single abstract method declaration can be the result of inheriting multiple declarations of the abstract method from superinterfaces.

All except `IA` are functional interfaces. `IA` does not define an abstract method, as it provides only an abstract method declaration of the concrete `public` method `equals()` from the `Object` class. `IB` defines a single abstract method, `doIt()`. `IC` overrides the abstract method from `IB`, so effectively it has only one abstract method. `IC` inherits the abstract method `doIt()` from `IB` and overrides the `equals()` method from `IA`, so effectively it also has only one abstract method.

Q16 (f)

The date value `2015-01-01` in the `date` reference never changes. The `withYear()` method returns a new `LocalDate` object (with the date value `0005-01-01`) that is ignored. The `plusMonths()` method also returns a new `LocalDate` object whose value is printed. The calculation of `date.plusMonths(12)` proceeds as follows: `2021-01-01 + 12 months (i.e., 1 year) ==> 2022-01-01`

Q17 (a), (d), and (f)

The input string matches the pattern. The input string specifies the time-based values that can be used to construct a `LocalTime` object in (a) by a formatter, based on the time-related pattern letters in the pattern. No date-based values can be interpreted from the input string, as this pattern has only time-related pattern letters. (b) and (c), which require a date part, will throw a `DateTimeParseException`.

To use the pattern for formatting, the temporal object must provide values for the parts corresponding to the pattern letters in the pattern. The `LocalTime` object in (d) has the time part required by the pattern. The `LocalDate` object in (e) does not have the time part required by the pattern, so an `UnsupportedTemporalTypeException` will be thrown. The `LocalDateTime` object in (f) has the time part required by the pattern. In (f), only the time part of the `LocalDateTime` object is formatted.

Q18 (a)

A `Thread` object executes the `run()` method of a `Runnable` object in a separate thread. A `Runnable` object can be provided when constructing a `Thread` object. If no `Runnable` object is supplied, the `run()` method of the `Thread` object (which implements the `Runnable` interface) is executed. A thread is initiated by calling the `start()` method of the `Thread` object.

Q19 (b) and (d)

In (a), the class need not be declared as a generic type if it defines any generic methods.

In (b), the method `choose(T, T)`, where `T` extends `Comparable<T>`, is not applicable to the arguments `(Integer, String)`. Note that `Object` is not `Comparable<Object>`.

In (c), the method `choose(T, T)`, where `T` extends `Comparable<T>`, is not applicable to the arguments `(Integer, Double)`. Note that `Number` is not `Comparable<Number>`.

In (d), the actual type parameter `Double` specified in the method call also requires that the `int` argument is cast to a `double` in order for the call to be valid. The method `choose(T, T)`, where `T` extends `Comparable<T>`, is then applicable to the argument list `(Double, Double)`.

(e) cannot convert the `Double` returned by the method to an `int` using a cast.

In (f), the method returns a `Double` that is first converted to a `double`, which in turn is converted to an `int`.

Q20 (a) and (d)

Field `b` of the outer class is not shadowed by any local or inner class variables; therefore, (a) will work. Using `this.a` will access field `a` in the inner class. Using `this.b` will result in a compile-time error, since there is no field `b` in the inner class. Using `Outer.this.a` will successfully access the field of the outer class. The statement `c = c` will only reassign the current value of the local variable `c` to itself.

Q21 (a)

All enum types implement the `Comparable` interface. Comparison is based on natural order, which in this case is the order in which the constants are specified, with the first one being the smallest. The ordinal value of the first enum constant is 0, the next one has the ordinal value 1, and so on.

Q22 (c) and (d)

Executing synchronized code does not guard against executing non-synchronized code concurrently.

Q23 (a), (c), and (e)

Lists of type `Pet`, `Dog`, and `Cat` are subtypes of `List<? extends Pet>`, `List<? extends Wagger>` and `List<?>`.

`List<? super Pet>` is a supertype for a list of `Pet` itself or a supertype of `Pet`—for example, `Wagger`, but not `Dog` or `Cat`.

`List<? super Wagger>` is a supertype for a list of `Wagger` itself or a supertype of `Wagger`—for example, `Object`, but not `Pet`, `Dog`, or `Cat`.

Q24 (c)

We need to access the following:

- `Importing.JPEG` (to print `200`).
- `p1.Util.Format.JPEG` (to print `Jpeggy`). Since `p1.Util.Format` is statically imported by the second import statement, we need only specify `Format.JPEG`.
- `p1.Format.JPEG` (to print `JPEG`), which is explicitly specified to distinguish it from other `JPEG` declarations.

Q25 (b)

First, note that the `indexOf()` method returns the index of the *first* occurrence of its argument in the list. Although the value of variable `i` is successively changing during the execution of the loop, it is the *first* occurrence of this value that is replaced in each iteration:

Click here to view code image

```
                          0      1     2

                        [2019, 2020, 2021]
  After iteration 1: [2020, 2020, 2021]
  After iteration 2: [2021, 2020, 2021]
  After iteration 3: [2022, 2020, 2021]
```

Note also that we are not removing or adding elements to the list, only changing the reference values stored in the elements of the list.

Q26 (c)

Note that only `GraduateStudent` is `Serializable`. The field `name` in the `Person` class is `transient`. During serialization of a

`GraduateStudent` object, the fields `year` and `studNum` are included as part of the serialization process, but not the field `name`. During deserialization, the default constructors of the superclasses up the inheritance hierarchy of the `GraduateStudent` class are called, as none of the superclasses are `Serializable`.

Q27 (c), (d), (g), and (h)

The method header signature of the corresponding methods is the same after erasure—that is, `List fuddle()` and `List scuddle(Object)`. The return type of overriding methods can be a raw type or a parameterized type.

Q28 (d)

A `try` block must be followed by at least one `catch` or `finally` clause. No `catch` clause can follow a `finally` clause. Methods must declare any checked exceptions in a `throws` clause, if they do not catch the exceptions.

Q29 (a), (b), and (c)

First, note that nested packages or nested static members are not automatically imported.

In (d), `p2.DefenceInDepth` is not a static member and therefore cannot be imported statically.

With (e), `March.LEFT` becomes ambiguous because both the second and the third import statements statically import `March`. The enum constant `LEFT` cannot be resolved either, as its enum type `March` cannot be resolved.

With (f), the enum constant `LEFT` cannot be resolved, as none of the static import statements specify it.

The enum type `p2.March` is also not visible outside the package.

Q30 (b)

Statement (c) is `false`, since an object of `B` can be created using the implicit default constructor of the class. `B` has a default constructor since no constructor has been defined. Statement (d) is `false`, since the second constructor of `C` will call the first constructor of `C`.

Q31 (c)

The important thing to remember is that an instance of a class is also an instance of its superclasses in the inheritance hierarchy.

Q32 (d)

Enum constants can be used as `case` labels and are not qualified with the enum type name in the `case` label declaration. The `switch` selector expression is compatible with the `case` labels, as the reference `this` will refer to objects of the enum type `Scale5`, which is the type of the `case` labels. The call to the method `getGrade()` returns a `char` value, which in this case is `'C'`.

Q33 (b) and (g)

The method in (a) and the method at (1) do not have the same or covariant return types required for overriding.

The method in (b) overrides the method at (2).

The instance method in (c) cannot override the static method at (4).

The static method in (d) and the static method at (4) do not have compatible return types for overriding.

The static method in (e) cannot hide the instance method at (3).

The instance method in (f) and the instance method at (5) do not have compatible return types for overriding.

The instance method in (g) overrides the instance method at (6), and they have covariant return types.

Q34 (c)

A primitive value cannot be widened and then boxed implicitly. The primitive value is boxed to its corresponding wrapper type, and an attempt is made to find a corresponding formal parameter with the most specific type to which it can be passed. The varargs value is passed in the method calls as follows:

Click here to view code image

```
printFirst(10);           // new Integer[] {Integer.valueOf(10)}
printFirst((byte)20);     // new Number[] {Byte.valueOf(20)}
printFirst('3', '0');     // new Object[] {Character.valueOf('3'),
                          //               Character.valueOf('0')}
printFirst("40");         // new Object[] {"40"}
printFirst((short)50, 55);// new Number[] {Short.valueOf(50),
                          //               Integer.valueOf(55)}
printFirst((Number[])new Integer[] {70, 75}); // Passed as array of Number
```

Q35 *(e)*

The program will compile and print `1`, `3`, and `2` at runtime. First, the static initializers are executed when the class is initialized, printing `1` and `3`. When the object is created and initialized, the instance initializer block is executed, printing `2`.

Q36 *(a)*

As there is no appropriate resource bundle file for the `no_NO` locale, the resource bundle for the default locale (US) is loaded. The value of the key `"greeting"` from this resource bundle is printed. Changing the default locale of the application does not change the locale associated with the resource bundle `rbs`. The value of the key `"greeting"` from this resource bundle is printed one more time.

Q37 *(e)*

The `runner` thread can only proceed if `intArray[0]` is not `0`. If this element is not `0`, it has been initialized to `10` by the main thread. If this element is `0`, the `runner` thread is put into the wait set of the `intArray` object, and must wait for notification. The main thread only notifies after initializing both elements of the array to `10`. Calling the `notify()` method on an object with no threads in its wait set does not pose any problems. A thread can only call `notify()` on an object whose lock it holds. Therefore, the last `synchronized` statement in the `main()` method is necessary.

Q38 *(b)*

Notice that the array is declared as a raw type, yet the objects that are placed into this array are of a parameterized type. This is a legal assignment because an object of a parameterized type can be assigned to a raw type variable, in this case an element within the raw type array. However, in this case the `compareTo()` method accepts an argument of type parameter `T`, which allows invocation of any `Object` method using a reference of this type parameter. The code in the `compareTo()` method invokes the `toString()` method to convert each value into a `String` object and then compare these strings. The order of the comparison is therefore not numeric, but lexicographical. Note that the raw type `Thingy` is also used in the `for(:)` loop.

Q39 *(c)*

Each lambda expression implements a `Comparable` that returns an `int` value. These `int` values are accumulated and stored in the static field `result` of class `Widget`. The first lambda expression returns the length of the `"ACME"` string (i.e., 4), the second lambda expression returns the index of letter `"C"` within the string `“ACME"` (i.e., 1), and the third expression returns the day of the month in the `LocalDate` object (i.e., `20`). The sum in the `result` field is thus `25`, which is printed.

Q40 (b)

The `sort()` method of the `Arrays` class sorts the elements of the `Integer` array according to the total ordering defined by the `Comparator<Integer>` that is implemented by the lambda expression. The difference `x - y` between two values `x` and `y` determines whether `x` is less than, equal to, or greater than `y`, according to the contract of the `compare()` method of the `Comparator<E>` interface. The elements of the array are sorted in ascending order.

Q41 (a)

The `LocalDate` class uses the ISO-8601 standard, where year 0 corresponds to 1 BC. The pattern `"dd MM yy G"` results in the number of the day in the month, the short name of the month, the two-digit value of the year, and BC/AD being used to format the local date.

Q42 (c)

Stream processing distinguishes `LocalDateTime` objects from all other objects. It extracts the number of seconds from a `LocalDateTime` object, substitutes 1 for all other elements in the stream, and calculates the sum for all the elements. There is only one `LocalDateTime` object in this stream, which yields the value of `2`; the other four objects are substituted with a value of `1` in the stream. Thus the result is `6`.

Q43 (d)

The text block has two incidental leading whitespace on each line that are removed. After the removal of the two incidental spaces from all lines, the line lengths in the text block are 1, 3, and 1. The resulting string literal is `"a\n b\nc\n"`.

Q44 (c)

The paths constructed by the code are as follows:

Click here to view code image

```
p1: /users/joe
p2: /users/bob
p1.relativize(p2):                  ../bob
p3 = p1.resolve(p1.relativize(p2)): /users/joe/../bob
```

```
p4 = p3.normalize():                  /users/bob
```

Since the first component of a path has index 0, index 1 refers to `joe` in `p3` and `bob` in `p4`.

Q45 (b)

The resource bundles are loaded from the files `resources_en.properties` (which has an entry for key `f2`) and `resources.properties` (which has an entry for key `f1`). The `resources_en_GB` bundle is not loaded by the `getBundle()` method.

When the value for key `f1` is not present in the `resources_en` bundle, the parent bundle `resources` is searched for the value of key `f1`. The `en_GB` locale is applied to the formatter, which uses the value `"yy-MMM-dd"` of key `f1` to format the date.

Q46 (b)

The `action()` method uses short-circuit conditional operators `||` and `&&` to test whether the parameter `obj` is a `String` or an `Integer`. The `instanceof` pattern match operator only introduces a pattern variable if it evaluates to `true`. If it is a `String`, it checks whether this string contains the character `'1'`. Otherwise, it checks whether the parameter `obj` is an `Integer`, and if it is, it determines whether its value is less than 1. The object passed to the method is an `Integer` object with a value of 1, which is not less than 1, and thus the `boolean` expression returns `false`.

Q47 (c)

A non-canonical constructor is required, since the arguments passed in the constructor are of type `String` and `int`, and not `String` and `Duration`, as in the declaration. The first statement in a non-canonical constructor must be an explicit invocation of a constructor with the `this()` expression that leads to the canonical constructor being invoked so that the component fields `title` and `duration` are initialized.

(a) and (b) are incorrect because they do not provide a value for the `title` field. Moreover, in (a), the `this` reference cannot be used in a `this()` expression.

(d) and (e) do not invoke the canonical record constructor with the `this()` expression.

(c) fulfills all the requirements.

Q48 *(b)*

The `walk()` method navigates the directory structure for the directory `./Sun`. The `map()` method extracts the name of the leaf element from each `Path` that is encountered in this depth-first walk in the directory tree. The names are sorted. Notice that although the names start with a character that represents a number, the natural ordering is that for strings.

The `limit()` method limits the length of the stream to just the first three elements. Given the natural ordering for strings, the first three elements in the list are `1_Io`, `1_Mercury`, and `1_Moon`. The `forEach()` operation prints a substring extracted from the name starting at index 2.

Q49 *(b)*

The method `lines()` creates a stream of text lines read from the text file. Lines are grouped on the substring extracted from each line after the `':'` character. The map created by grouping has these substrings as keys and the lines containing the key as values. All lines that end with 1.70 will be grouped together, all lines that end with 1.99 will be in another group, and so on.

Q50 *(c)*

Module `basic` is the service provider as it implements the service defined by the service interface `TransportType` in module `transport`. Module `basic` requires module `transport` and must declare that it provides an implementation (`basic.mode.Horse`) of the service interface `transport.mode.TransportType`.

The `requires` directive must specify modules, not packages, as in (b) and (d). (a) requires the wrong service module and implements the wrong service interface.

Appendix G

Java Logging API Overview

The Java Logging API is a supplementary topic, and *not* an exam objective. However, there could be some exam questions that utilize the Logging API to facilitate non-blocking parallel processing, such as in parallel streams. Also, an understanding of the Logging API principals and capabilities is an important practical programming skill.

G.1 Purpose of the Logging API

The purpose of the Java Logging API is to provide a simple yet flexible mechanism for writing logs to different destinations, while minimizing the effects of writing these logs on the overall performance of a Java application. A program can write messages to the standard output or standard error using `System.out` or `System.err`, respectively. However, this approach is not particularly flexible, because such write operations block the current thread. Thus they adversely affect program performance, and are totally unsuitable in any concurrent or parallel execution of code—for example, in parallel stream processing. Using standard out and standard error is also not very flexible because they do not allow a programmer to reconfigure the target destination for the log messages, nor do they provide a flexible dynamic mechanism to filter or format log messages.

The Logging API addresses the following issues:

- Provides a *configuration properties file* to configure:

    - *Log handlers*, which write log messages to different destinations
    - *Log message format* for each destination
    - *Logging levels*, which control how detailed logging should be done

- Minimizes performance implications with:
    - *Non-blocking* log writing operations
    - *Guarded logging*, which avoids unnecessary message formatting when the logger level is set in a way that a particular message is not going to reach the actual log destination

G.2 Configuring Logging

By default, the file `logging.properties` is used to configure Java logging. It is located in the `JAVA_HOME/conf` folder. (For Java version 8 or earlier, this was `JAVA_HOME/jre/lib` folder.) A different configuration file can be specified using the `java.util.logging.config.file system property`. For example:

Click here to view code image

```
java -Djava.util.logging.config.file=another-config
```

Log handlers are classes that are responsible for writing log messages to different destinations. The package `java.util.logging` provides a number of handler classes. A *logger configuration file* can be used to enable one or more handlers specified as a comma-separated list. By default, the logger configuration only sets up the *console handler*, but other handlers can be enabled as required. For example:

Click here to view code image

```
handlers = java.util.logging.FileHandler, java.util.logging.ConsoleHandler
```

Each handler has its own specific configurable properties. For example, a file handler allows setting up a naming pattern for log file names, minimum size of the file, log rollover to the next file, and so on. For example:

Click here to view code image

```
java.util.logging.FileHandler.pattern = %h/java%u.log
java.util.logging.FileHandler.limit   = 50000
java.util.logging.FileHandler.count   = 1
```

Obviously, such properties are not applicable to other types of handlers, such as the console handler. However, all handlers provided by the Java Logging API allow a logger format to be set; for example, as a simple plain text or xml format.

Click here to view code image

```
java.util.logging.ConsoleHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.formatter    = java.util.logging.XMLFormatter
```

It is possible to implement customized handlers by extending the `java.util.logging.Handler` class or one of its subclasses: `MemoryHandler` or `StreamHandler`. Also, it is possible to implement a customized formatter by extending the `java.util.logging.Formatter` class.

Level configuration is used to control the number of messages that are actually written to a log destination. *Logging levels* are defined by the `java.util.logging.Level` class using the following constants:

```
SEVERE (highest value)
WARNING
INFO
CONFIG
FINE
FINER
FINEST (lowest value)
```

In addition, there is a level `OFF` that can be used to turn off logging, and a level `ALL` that can be used to enable logging of all messages.

When logging is set to a certain logging level, any log message that is associated with this logging level and levels above it will be written to the log destination. However, messages that are associated with any logging levels below the one that was set in the configuration will essentially be ignored by the logger.

For example, when the log level is set to `INFO`, the `INFO`, `SEVERE`, and `WARNING` level messages will be written to the log, but the `CONFIG`, `FINE`, `FINER`, and `FINEST` level messages will be ignored by the logger.

It is possible to implement additional logging levels by subclassing the `java.util.logging.Level` class.

Log level configuration defines a *global log level property*, but also allows overriding the level for specific loggers. For example:

```
.level=INFO
org.foo.level=SEVERE
```

It is important to note that by convention, logger names are essentially Java packages and class names. So this example implies that everywhere in the program, the global logger level is `INFO`, except for the package `org.foo`, where it is set to `SEVERE`.

It is also possible to set the logging level for a specific handler. For example:

Click here to view code image

```
java.util.logging.ConsoleHandler.level = WARNING
```

Suppose that logging has been configured to use a file logger and the console logger, and the console logger is restricted to the `WARNING` level, but no such restriction is imposed on the file logger. Also, assume that the global log level is set to `INFO`. This would mean that log messages associated with a level below `INFO` would all be ignored; only `WARNING` and `SEVERE` level message would be written to the console logger; and `INFO`, `WARNING`, and `SEVERE` level messages would be written to the file logger.

G.3 Writing Log Messages

To set up logging for a program requires a few basic steps. First, a logger object must be initialized, using the `java.util.logging.Logger.getLogger(String name)` method. By convention, the name of a logger object should correspond to the fully qualified class name from which the log is written. This way, it will match the logger naming convention used by the logger configuration file. For example:

Click here to view code image

```
package org.foo;
import java.util.logging.*;
public class Test {
  private static Logger logger = Logger.getLogger(org.foo.Test.class.getName()
  public static void main(String[] args) {
  ...
  }
}
```

Notice that the logger name could theoretically be any string.

However, using package and class names really helps to organize logger configuration. In this case, a logger config file can associate the `org.foo` logger name with a particular level of logging, which is going to affect log messages written from the `org.foo.Test` class.

Once the logger object is initialized, it can be used to write messages, using the `logger.log()` method. Each message is associated with a specific logger level and may contain any text. The `log()` method is overloaded to allow the program to pass an exception object as an additional argument so that exception details can be passed to the logger as part of the message. For example:

Click here to view code image

```
package org.foo;
import java.util.logging.*;
public class Test {
  private static Logger logger = Logger.getLogger(org.foo.Test.class.getName()
  public static void main(String[] args) {
    try {
      // any actions that may potentially throw an exception
    }catch(Exception e) {
      logger.log(Level.ERROR, "Some error message", e);
    }
    logger.log(Level.INFO, "Some other message");
  }
}
```

The `Logger` class provides a number of additional convenience methods that are equivalent to the `log()` method:

> `logp()`
>
> The *log precise* method takes additional parameters that specify a class and a method name.
>
> `logrb()`
>
> The *log with resource bundle* method takes a resource bundle name that may be used to localize log messages.
>
> `entering()`, `exiting()`, `throwing()`
>
> These are convenience methods used to log method entry, method exit, and any exception thrown at the `FINER` level.
>
> `severe()`, `warning()`, `config()`, `info()`, `fine()`, `finer()`, `finest()`
>
> These are convenience methods, each hardcoded to use a specific log level, rather than indicating the log level as an argument. In other words, `logger.info("My message")` is equivalent to `logger.log(Level.INFO, "My message")`.

All of these log methods are *non-blocking*. This means that when any of these log methods are invoked in the program, the current thread is not blocked, as the method call returns immediately. The logger accumulates messages produced by the different program threads, and writes these messages to the actual destinations in another thread of its own. As a result, the log messages can reach their destinations with a minimum of delay, but the performance impact on the overall program execution is minimized. This allows loggers to be utilized in concurrent and parallel execution scenarios.

G.4 Applying Guarded Logging

Finally, it is a good idea not to format log messages ahead of time. This is because it is not known whether the message would or would not be written into a log because of the possible changes to the logger configuration. This means that code in the following example is not advisable:

Click here to view code image

```
logger.log(Level.FINE, "This is " + someVar + " value");
```

In the preceding code, message concatenation is going to be performed even if the log level could be set in a way that would ignore this message. In order to prevent such unnecessary processing, it is advised to use *guarded logging*. Basically, the aim is not to do message formatting when the message is going to be discarded because of the log level settings. This could be achieved with an `if` statement or by using *message value substitution*. For example, the following `if` statement:

Click here to view code image

```
if(logger.isLoggable(Level.FINER)) {                         // (1)
  logger.log(Level.FINE, "This is " + someVar + " value");
}
```

can be witten using message value substitution:

Click here to view code image

```
logger.log(Level.FINE, "This is {0} value", someVar); // (2)
```

Notice that the code at (2) looks much cleaner than the code at (1) and is thus probably the best way to handle log messages.

G.5 Summary

The Logging API provides a simple, yet flexible non-blocking mechanism to write information about program execution, including general information as well as error messages. The certification exam does not ask any direct questions about logging, but use of loggers may be encountered in the context of other questions, specifically where non-blocking output is important, such as in the context of the Concurrency API or execution of parallel streams.

Code Snippets

Many titles include programming code or configuration examples. To optimize the presentation of these elements, view the eBook in single-column, landscape mode and adjust the font size to the smallest setting. In addition to presenting code and configurations in the reflowable text format, we have included images of the code that mimic the presentation found in the print book; therefore, where the reflowable format may compromise the presentation of the code listing, you will see a “Click here to view code image” link. Click the link to view the print-fidelity code image. To return to the previous page viewed, click the Back button on your device or app.

int diceValue = 1 + (int)(Math.random() * 6.0);  // A dice roll in range [1 .. 6]
```

`Math.random()`: `{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9}`
Multiply by 6: `{0.0, 0.6, 1.2, 1.8, 2.4, 3.0, 3,6, 4.2, 4.8, 5.4}`
Convert to `int`: `{0,   0,   1,   1,   2,   3,   3,   4,   4,   5}`
Add offset 1: `{1,   1,   2,   2,   3,   4,   4,   5,   5,   6}`

```
int     nextInt()
int     nextInt(int bound)
long    nextLong()
float   nextFloat()
double  nextDouble()
boolean nextBoolean()
```

```
Random generator = new Random();
```

```
int number = generator.nextInt();
```

```
number = generator.nextInt(11);      // Random integer in the interval [0, 10]
number = 2 + generator.nextInt(11);  // Random integer in the interval [2, 12]
number = 2 + 3*generator.nextInt(5); // Random integer in the set {2, 5, 8, 11, 14}
```

```
int diceValue = 1 + generator.nextInt(6);  // A dice value in the interval [1, 6]
```

```
Random persistentGenerator = new Random(31);
```

```
The BigDecimal  3.14   has unscaled value =  314   and scale = 2.
The BigDecimal -3.1415 has unscaled value = -31415 and scale = 4.

}
```

```
(1) Create an empty list of strings:
[]

(2) Add elements to list:
[0:level]
[0:level, 1:Ada]
[0:level, 1:Ada, 2:kayak]
[0:level, 1:Ada, 2:kayak, 3:Bob]
[0:level, 1:Ada, 2:kayak, 3:Bob, 4:Rotator]
[0:level, 1:Ada, 2:kayak, 3:Bob, 4:Rotator, 5:Bob]
Insert an element at index 2 in the list:
[0:level, 1:Ada, 2:Java, 3:kayak, 4:Bob, 5:Rotator, 6:Bob]
```

```
(3) Replace the element at index 1:
Element that was replaced: Ada
[0:level, 1:Naan, 2:Java, 3:kayak, 4:Bob, 5:Rotator, 6:Bob]

(4) Remove the element at index 0:
Element removed: level
[0:Naan, 1:Java, 2:kayak, 3:Bob, 4:Rotator, 5:Bob]

(5) Remove the first occurrence of "Java":
Element removed: true
[0:Naan, 1:kayak, 2:Bob, 3:Rotator, 4:Bob]

(6) Determine the size of the list:
The size of the list is 5

(7) Determine if the list is empty:
The list is not empty.

(8) Get the element at specific index:
First element: Naan
Last element: Bob

(9) Compare two lists:
The lists strList and strList2 are equal.
[0:Naan, 1:kayak, 2:Bob, 3:Rotator, 4:Bob, 5:null]
The lists strList and strList2 are not equal.

(10) Sublists as views:
Underlying list: [Naan, kayak, Bob, Rotator, Bob]
Sublist before remove: [kayak, Bob, Rotator]
Remove: kayak
Sublist after remove: [Bob, Rotator]
Underlying list: [Naan, Bob, Rotator, Bob]

(11) Membership test:
The list contains the string "Naan".

(12) Find the index of an element:
The index of string "Bob" is: 1
The index of string "BOB" is: -1
The last index of string "Bob" is: 3
[0:Naan, 1:Bob, 2:Rotator, 3:Bob]

(13) Iterating over the list using the for(;;) loop:
0:Naan 1:Bob 2:Rotator 3:Bob

(14) Iterating over the list using the for(:) loop:
Naan Bob Rotator Bob

(15) Convert list to array:
Object[] length: 4
Length of each string in the Object array: 4 3 7 3
String[] length: 4
Length of each string in the String array: 4 3 7 3
